

Drying tunnel

Clear, clean and functional

Kingfisher tunnels allow to constantly monitor the hides from the beginning to the end of the drying process.

Part of the front doors are made of very low transmittance glass and the inside of the tunnel is illuminated. This allows to the line operators to constantly monitor the correct drying of the hides and to have immediate feedback on the presence of impurities.

Steam tunnel

Constant and filtered ventilation

The heat is conveyed to the grain of the leather in a uniform and constant way. The presence of the upstream and downstream heat exchanger air filters guarantees a clean and well-distributed airflow.

The motors connected to the fans are managed by inverters and therefore have a variable speed. The airflow can be modulated according to the type of leather to be processed and according to the chemical product to be dried.

Large doors on both sides of the tunnel allow the easy extraction of the air filters and the easy access for internal cleaning when necessary.
